Introduction

We are in the midst of a paradigm shift impacting the food industry. Taking a proactive wellness stance, consumers increasingly focus on the nutrition in the foods they consume. People, especially the millenials, more closely examine the impact of food not only on their health and wellness but also on the environment. Some are also concerned about the relationship between food and animal welfare as well as resource scarcities.

The for-profit companies profiled in this book are leading the reinvention of condiments and food. Sustainable, profitable, scalable firms that create better products will gain market share and ultimately win out, at least among more discerning consumers.

Riding the link between salt and high blood pressure, heart disease, and stroke, as espoused by the public health officials, the first part of this book, Chapter 1, examines Nu-tek Food Science, which sells a salt substitute. Using a patented process, its products reduce sodium chloride content by up to 75 percent, yet deliver the same taste as traditional salt.

The second part of the book, Chapter 2, begins by critically examining the animal welfare, human health and wellness, resource scarcities, and environmental impact factors on which firms profiled in this part base their products. With perception sometimes trumping the reality with respect to certain of these factors, a ready market exists for animal product substitutes, among some consumers. Chapters 3 to 7 analyze five startup firms that display culinary entrepreneurship combining environmental and vegan ethics, an interest in human health and wellness, a commitment to taste and texture, and a belief that technology and money can improve the world. Each wants to revolutionize what we eat.

These five companies, Lyrical Foods (Chapter 3), Hampton Creek (Chapter 4), Beyond Meat (Chapter 5), Impossible Foods (Chapter 6), and Modern Meadow (Chapter 7) seek to disrupt the annual global trillion dollar animal agricultural industry. Each wants to create healthier and more sustainable products amid concerns about climate change and resource constraints.

Based on the use of various transformative technologies, each of these firms offers a new era for the

animal products most of us currently eat. The five companies want to give consumers the tastes, textures, looks, and aromas together with the nutritional benefits of foods coming from animals but without the negative human health and environmental aspects.

Four of the firms currently engineer plant-based products that replicate cheeses (Lyrical Foods), eggs (Hampton Creek), and meat (Beyond Meat and Impossible Foods). While initially focused on leather, Modern Meat ultimately looks to develop lab-grown meat, synthesized from animal stem cells.

Although picking winners and also-loses represents a difficult endeavor, some of these startups will emerge to challenge traditional food conglomerates that are not as nimble. Although Kellogg owns the vegetarian food giant Morningstar Farms, the largest veggie food producer in the United States, and Kraft has its Boca Foods brand, each of these five companies wants to out-innovate established food firms. In so doing, they open a new era for alternative animal products, indistinguishable for the real thing, but healthier, more sustainable amid mounting environmental

concerns and resource constraints, and hopefully as or less expensive.

The third part, Chapter 8, considers the most revolutionary of the efforts - an all-in-one product - Soylent, sold by Rose Labs. It would replace grocery shopping and cooking with a liquid meal. The chapter critically considers the benefits and drawbacks of this relatively inexpensive, but efficient food substitute.

As scientists and entrepreneurs seek to remake our relationship with animals and the planet, policy issues run throughout parts two and three of this book. Specific policy issues include the U.S. Food and Drug Administration's standards for products, such as mayonnaise (Chapter 4), as well as the federal government's regulation of cultured meat (Chapter 7) and dietary supplements (Chapter 8). More generally, a federal regulatory framework must evolve to meet how people are now starting to eat substitute animal products. The possible consolidation of the food safety inspection system into one federal agency is discussed in Chapter 9.

Beyond scientists, entrepreneurs, and government regulators, funders evidence an interest in these non-

traditional food startups. With products that help solve big problems - health, environment, food safety, animal welfare, and resource scarcities - and transform the food industry, venture capital firms have gotten involved as funders. These investors in high profile tech startups do not think small; they want to change the world. A group of major venture capital firms, including Khosla Ventures, Kleiner Perkins Canfield & Byers, and Andreessen Horowitz, as discussed in Chapters 1, 3 through 8, have made a variety of big bets on food and condiments.¹ Bill Gates² and PayPal co-founder and venture capitalist Peter Thiel's Breakout Labs and Founders Fund are also in the game. Investments by venture capital firms and technology pioneers have given the alternative food industry a tremendous shot of credibility.

Along with scientists and entrepreneurs, these venture capitalists, both firms and individuals, want to transform the food industry and its current, broken impact on human health, the environment, and animals. Fixing it requires innovation and the redesign of systems and processes. For some, food-related startups fit along with other health and wellness investments. Because they seek to lessen the

adverse environmental impact of producing animal products, others see their investments fitting into their sustainability portfolios, along with solar energy. These venture capitalists do not see innovations emerging from major food conglomerates; rather, they look to startups pioneering innovations. They want to fund something small, see it iterate rapidly, sometimes even having programmers writing code to test plant species, and scale it up. In short, these food startups may behave similarly to the most successful tech companies.³

Tackling real world problems and transforming the food industry represents an audacious challenge. As Amol Deshpande, a partner in Kleiner Perkins who specializes in agricultural technology, stated, “Being able to change the game in terms of how we deliver protein to the growing population is probably the biggest thing anybody could do.”⁴

Chapter 9 provides a brief conclusion noting that in the future we may see both plant-based animal products alongside more humanely and sustainably raised animals and less-meat intensive diets.

I. Replacing a Key Condiment

1. Salt and Its Substitutes: Nu-Tek Food Science

Salt saturates our food supply, particularly processed foods including deli meats, canned goods, such as soup, and pizza. This chapter summarizes the studies dealing with the impact of salt consumption on long-term health.

Although the impact remains controversial, Nu-Tek Food Science offers two products to meet the demand for reduced salt—sodium chloride—by the food industry, restaurant owners, and the public.

Health Reasons to Reduce Salt Intake

For decades, medical experts have advocated that humans reduce their salt—sodium chloride—intake. They have told individuals, especially those suffering from high blood pressure, those 50 years of age or older, African-Americans, and those who have diabetes or chronic kidney disease, to reduce their salt consumption to lower their blood pressure. Public health officials have long presented the link between salt and heart disease as an established fact.

The problem is sodium, one of the chemical elements in salt. However, not all sodium is bad. Some sodium is essential to good human health. Sodium helps maintain the correct balance of bodily fluids and transmit nerve impulses as well as influence muscle contraction and relaxation.¹

A much-cited study carried out by the National Institutes of Health, the DASH (Dietary Approaches to Stop Hypertension)-sodium study,² found that participants put on lower sodium intake diet than the control group, in conjunction with the DASH diet, ended up with significantly lower blood pressure, with a greater impact of the diet and lower sodium consumption in combination than each singly. This study led to public health pronouncements demonizing salt. For example, 2010 Dietary Guidelines for Americans, jointly issued by the U.S. Department of Agriculture and the U.S. Department of Health and Human Services, put salt at the top of the list of things to avoid based on "[a] strong body of evidence in adults that documents as sodium intake decreases, so does blood pressure."³

The reason to avoid salt: The more salt we eat, the more water our body retains, and the more our blood volume

increases. Water retention makes our hearts work harder, increases our blood pressure until our kidneys flush out the water and the salt. Thus, anti-salt proponents believe that salt has long lasting impact on blood pressure. The ingestion of too much salt over a long time period will result in hypertension and possibly premature death resulting from heart disease, stroke, and kidney failure. Conversely, lowering salt intake would reduce blood pressure, which, in turn, would automatically lower the risk of heart and blood vessel diseases. In short, this hypothesis leads to the conclusion that lower salt intake in the general population, particularly among those who are sodium sensitive, would be beneficial.

Unsuccessful Salt Substitutes

Salt substitutes are not new. Products, such as Nu-Salt, AlsoSalt, and NoSalt, have been on the market for years. Salt replacement manufacturers removed sodium chloride from their products, replacing (or mixing) it with small amounts of potassium chloride to achieve a blood pressure lowering impact.⁴ They used expensive flavor enhancers to mask the unpleasant, often bitter metallic

taste of the substitute minerals, which otherwise would ruin a product's taste.⁵ Processed food producers typically try to mix a potassium chloride salt substitute with other ingredients. Because the different flavor components hit the tongue at different times, eaters usually pick up the metallic taste. Other firms try pressing all the materials together, but they come apart in food processing and the metallic taste appears again. Swapping potassium chloride for sodium chloride also throws other ingredients, such as sugar and fat, in processed foods out of whack. With the strength of these other ingredients diminished, processors add more sugar and fat, to maintain, if not enhance, their products' allure.⁶

Nu-Tek Food Science

Nu-Tek Food Science, LLC (Nu-Tek), founded in 2006, offers potassium chloride products to meet the demand for reduced sodium chloride in the food industry, as well as by restaurant operators, and the general public. The firm has as its mission ``to help create great-tasting and

affordable food that enhances global health and wellness,’’⁷
and at the same time maintaining ‘‘great taste,
affordability, and ease of use.’’⁸

At present, Nu-Tek offers two products, NuTek Salt and Salt for Life.⁹ NuTek Salt is a product for food manufacturers and restaurant chains. According to Nu-Tek, some 10 of the top 13 global food producers have started incorporating the product. Salt for Life, which blends potassium salt, using its NuTek Salt process, with sea salt, targets health-conscious consumers.

Nu-Tek replaces a significant amount of sodium chloride in its NuTek Salt with a proprietary, unified crystal fashioned from potassium chloride and an organic acid, thereby achieving flavor uniformity. More specifically, Nu-Tek takes potassium chloride and sodium chloride, turns them into a wet slurry to dilute the mixture, blends the mixture with an organic acid, and recrystallizes it. Because the materials are no longer separated, but are bound together in a single crystal, ‘‘You don’t get that traditional bitter metallic note, and you can use [the salt replacement] at much higher levels.’’¹⁰

Initially, Nu-Tek sold its product to food processors that were getting serious about lessening the sodium chloride in their meat, poultry, cheese, bakery, spice blends, soups, sauces, and gravies. Nu-Tek's formula enabled these companies to reduce their products' sodium content by 30-50 percent and often in excess of 50 percent.¹¹ Thus, in meeting consumers' needs for low-sodium chloride products, food processors could offer consumers healthier products without changing their taste or functionality, at a minimal cost.

As the next step, the company rolled out its consumer friendly product to restaurant operators and then to the general public. Its Salt for Life can be used in the same way and in the same amounts as sodium chloride salt to season, cook, or bake. This salt replacement product, with 75 percent less sodium than common salt,¹² is available in a tabletop shaker, a retail-sized canister, and individual sachets. Consumers could obtain NuTek's Salt for Life initially on Amazon.com and beginning in 2013 in selected U.S. supermarkets. In 2015, it relaunched the brand, with a refreshed packaging design and a revamped logo.¹³

In addition to those who suffer from high blood pressure, in the future, Nu-Tek's consumer product may appeal to a more general public market. It will likely represent an option for people who have grown accustomed to ever higher amounts of salt in their diet, especially large amounts of salt in processed items.

Financing Nu-Tek

In February 2012, Khosla Ventures LLC, a leading information and green technologies venture capital firm, made a significant, but undisclosed, equity investment in Nu-Tek. The company used the funds to increase its infrastructure and overall capacity and to accommodate growing client demand and market needs for a reduction in sodium levels. Thomas L. (Tom) Manuel, Nu-Tek's Chief Executive Officer, noted, "This great partnership with Khosla Ventures will allow us to expand our capacity for our current customers and take advantage of the growing sodium-reduction market. With our improved potassium chloride technology, we are able to provide unmatched lower-sodium alternatives to our customers in a cost-

effective manner while maintaining the taste, flavor and functionality historically seen in processed foods.”¹⁴

Award Received

In 2013, the National Restaurant Association presented Nu-Tek’s Salt for Life Sea Salt Blend with one of its 2013 Food & Beverage Innovations Awards (FABI Award).¹⁵ The FABI Award recognized innovative consumable products delivering significant benefits to restaurant operators and the food industry. An independent panel of industry leaders, representing a variety of commercial and noncommercial food industry segments, selected the Salt for Life product for the award.

The Science Reconsidered

The DASH study represents one of the many that have examined the impact of salt intake on health. However, salt’s consumption on long-term health remains controversial. Two meta-analyzes, which summarize the results from many empirical studies, have raised doubts about the previous consensus of medical opinion.

Although finding that reducing salt intake leads to lower systolic blood pressure, one meta-analysis concluded

that "no strong evidence" exists that this will result in fewer premature deaths or a lower incidence of heart disease.¹⁶ Another meta-analysis concluded that "we do not know if low salt diets improve or worsen health outcomes."¹⁷

Other researchers go one step further than the second meta-analysis. They maintain that reducing salt intake increases one's risk of dying. The reason: the body needs a fair amount of sodium chloride daily. If a person gets too little sodium chloride, the kidneys secrete an enzyme, renin, which may have harmful effects on blood vessels and may lead to hypertension and cardiovascular disease.

Some studies have even found that low sodium intake was associated with an increase risk of heart failure. One recent study, what has become known as The Best Evidence Study,¹⁸ found that only the systolic (the top) blood pressure level slowly rises over time with increased salt intake. However, this rise did not translate into a higher risk for high blood pressure or heart and blood vessel disease. The study concluded:

The associations between systolic pressure [the top blood pressure number] and sodium excretion did not translate into less morbidity or improved survival. On the contrary, low sodium excretion

predicted higher cardiovascular [heart and blood vessel disease] mortality. Taken together, our current findings refute estimates of computer models of lives saved and health care costs reduced with lower salt intake. They also do not support the current recommendations of a generalized and indiscriminate reduction of salt intake at the [general] population level. However, they do not negate the blood-pressure lowering effects of a salt reduction in hypertensive patients.¹⁹

Two reasons may account for the death rates getting progressively worse in this study as salt intake decreased. First, low salt intake can lead to a loss of insulin sensitivity. As the definition of type 2 diabetes, this loss may represent a major factor in blood vessel inflammation, arteriosclerosis, and heart disease. Second, low salt intake can lead to insufficient production of digestive enzymes, which lead to the poor absorption of vitamins and minerals, possibly leading, in turn, to heart and blood vessel disease.²⁰

Others suggest that the key to heart health may rest on a low sodium-to-potassium ratio. The more potassium we consume, the more sodium is excreted through urine out of the body. Potassium also helps relax blood vessel walls, thereby lowering blood pressure. Too little potassium, in their view, is associated with cardiovascular problems.

Thus, a need exists for a therapeutic salt, such as Nu-Tek's products, with decreased sodium and increased potassium. However, too large amounts of potassium are linked to kidney problems, notably kidneys less able to remove potassium from the blood, especially for those taking medications for congestive heart failure or high blood pressure which often cause potassium retention.²¹

Despite the focus in this chapter on sodium and potassium, these elements are only some of the dietary factors that may affect blood pressure. Other factors include the type and amount of dietary fat, as well as levels of cholesterol, protein, fiber, calcium, and magnesium.

II. Substituting Animal Products: Cheese, Eggs, and Meat

2. Factors Driving the Development and Commercialization of Substitute Animal Products

This chapter surveys the four factors driving businesses to limit the damage from eating animal meat or animal by-products, such as milk and eggs, on our lives and on the planet: animal welfare; human health and wellbeing; resource constraints; and environmental impacts.¹ The chapter briefly analyzes the validity of each of these factors and assesses whether the traditional animal products have often alleged adverse impacts on our lives and on the planet.

Animal Welfare

Proponents of animal substitutes focus on animal welfare, specifically, treating animals as if they mattered, thereby reducing their suffering.² Building on the new morality that humans should not exploit animals for our own benefit, they also seek to heighten our guilt resulting from the consumption of sentient nonhuman beings who have intrinsic moral value.

Today, in factory-like farms and industrial feedlots, billions of chickens and cows spend their lives in inhumane, deplorable conditions. They are crammed into cages or pens. Packed in, body-to-body, even in enriched cages, so tightly that chickens cannot spread their wings. They are raised in their own waste, fed growth-enhancing chemicals, and eat antibiotic-laden soy and corn to help them grow until their slaughter. Egg-production systems involve killing unwanted one to three day-old male chickens. Male calves useless in the milk production industry are either killed shortly after birth or sent for veal production after castration and dehorning.

Even if animals are treated with compassion and attention to their well-being, being raised cage-free, with enhanced outdoor exercise, without growth hormones or antibiotics, chickens still face a frightening death with their flesh becoming food. Also, layer hens and dairy cows, among other animals, face elimination when their bodies are spent, their production drops, and they become burdensome. Thus, plant-based foods, including cheese, eggs, and meat, as well as lab-grown meat are viewed as the

way technology can help animals; especially as more meat lovers react to the horrors of confinement raising.

However, looking to plant-based substitutes would still result in the killing of animals of the field, such as rodents. Although accurate mortality numbers are unavailable, human actions by tractors and other farm implements run over animals. Plows and cultivators destroy their underground burrows and kill them. By removing ground cover, harvesting crops allows predators to kill small mammals on the surface.³ The application of pesticides, another type of human action, also kills animals of the field.

Human Health and Wellness

Plant-based cheese, eggs, and meat and lab-grown beef would promote human health and wellness in two ways: increasing food safety and improving human health.

Food Safety Concerns

Known foodborne pathogens, such as *E. coli* and salmonella, are responsible for some 9 (9.4) million illnesses, nearly 56,000 (55,961) hospitalizations, and

more than 1,300 (1,351) deaths each year in the United States alone. Unspecified foodborne agents account for an additional 38 (38.4) million illnesses, nearly 72,000 (71,878) hospitalizations and 3,000 (3,037) deaths annually in the United States.⁴ Nearly every test of supermarket chicken, for example, finds high percentages, sometimes reaching two out of every three samples, of staph, salmonella, or disease-causing antibiotic-resistant bacteria.⁵ By eating meat, especially where animals in close contact breed disease, humans are exposed to many virus-causing diseases, such as avian influenza.

The rampant use of antibiotics in the production of cows and chickens, among other animals, not only makes these drugs less effective but also encourages the development of hardier disease-causing bacteria. Every time animals receive antibiotics a chance exists that bacteria develop resistance to it. Resistant bacteria pass from animals to humans, primarily in the food chain. When animals are slaughtered and processed, bacteria in the meat can be carried into consumers' kitchens.⁶

Public Health Concerns

Public health concerns arise from eating animal products. There are two alleged culprits: cholesterol and fats, which raise the risk of myriad ailments, including heart disease, strokes, diabetes, and some cancers, at least we are told. In particular, some research points to the unhealthy consequences of red meat consumption. According to one study, after controlling for various variables, three additional ounces of unprocessed red meat a day was associated with a 12 percent greater risk of dying overall, a 16 percent higher risk of cardiovascular death, and a 10 percent greater risk of cancer death. Conversely, if the people in the study (n=121,342) had eaten one half as much meat, researchers estimated that deaths in the group would have declined 9.3 percent for men and 7.6 percent for women.⁷

Cholesterol

Physicians have long maintained that cholesterol, particularly high levels of LDL, the "bad" cholesterol, increases the risk of heart disease and stroke. For example, in 2002, the National Institutes of Health's National Cholesterol Education Program called elevated LDL-

cholesterol a “powerful risk factor” for cardiovascular disease.⁸ The 2010 Dietary Guidelines for Americans more cautiously noted, “Moderate evidence shows a relationship between higher intake of cholesterol and higher risk of cardiovascular disease.”⁹ Thus, LDL cholesterol represents the biomarker widely used to condemn saturated fat found in animal products.

However, studies have negated LDL-cholesterol as a meaningful predictor of the risk of heart attack, at least for most people.¹⁰ Cholesterol levels may have little or nothing to do with the amount of plaque in human arteries, the thickening of blood vessels, and the choking off of blood flow to the heart and thus with heart disease. Thus, Americans need not avoid egg yolks, liver, and shellfish, among other foods.

Saturated Fat

Physicians generally recommend a low-fat diet, keyed to avoiding saturated fat found, for example, in meat. Thus, tightly controlling the percentage and types of fat would improve the health benefits of plant-based or lab-grown animal products. These substitutes, particularly

meat and cheese, can be produced with limited amounts of saturated fat.

Since 1980, the Dietary Guidelines for Americans (Dietary Guidelines) have urged Americans to cut back on fat, particularly the saturated kind found in animal products, such as red meat, milk, cheese, and eggs.¹¹ These guidelines recommend replacing these foods with more fruits, vegetables, and grains. By 2010, the Dietary Guidelines backed off from mentioning any specific percentage limits on the total consumption of fat, only noting:

A strong body of evidence indicates that higher levels of most dietary saturated fatty acids is associated with higher levels of blood total cholesterol and low-density lipoprotein (LDL) cholesterol. Higher total and LDL cholesterol levels are risk factors for cardiovascular disease.¹²

However, the 2010 Dietary Guidelines ratcheted the allowable amount of saturated fat down to 7 percent or less of one's daily calories, not the 11 percent daily consumed by adults, so as to "further reduce the risk of cardiovascular disease."¹³ Although not explicitly stated in the Dietary Guidelines, by inference we should cut back on the amount of red and processed meat as well as cheese

consumed. The Dietary Guidelines recommend an increased intake of fat-free or low-fat cheese, both of which may taste "awful" and eating meat and poultry in lean forms, which often lack flavor and mouthfeel, to reduce fat consumption.¹⁴

Despite these guidelines, two massive clinical trials funded by the National Institutes of Health failed to show any benefits of a low saturated fat diet in improving human health.¹⁵ Two meta-analyses of all available evidence concluded that saturated fat does not cause heart disease.¹⁶ Conversely, according to another meta-analysis, current empirical evidence does not support cardiovascular guidelines encouraging the low consumption of total saturated fats.¹⁷

Thus, consuming animal products is not unquestionably bad for us.¹⁸ Saturated dairy fat, for instance, likely has some positive health benefits. One writer summarized evidence with respect to saturated fat as follows:

The sum of the evidence against saturated fat over the past half-century amounts to this: the early trials condemning saturated fat were unsound; the epidemiological data showed no negative association; saturated fat's effect on LDL-cholesterol (when properly measured in subfractions) is neutral; and a significant body of clinical trials over the past decade has

demonstrated the absence of any negative effect of saturated fat on heart disease, obesity, or diabetes. In other words, every plank in the case against saturated fat has, upon rigorous examination, crumbled away.¹⁹

Resource Scarcities

Animal products are seen as using too many resources, including land, water, and energy. Proponents raise the often-asked question: If the global population does not peak soon, how will we feed an estimated 9 billion people in 2050, up from the present 7.2 billion?²⁰

Today, each year, humans worldwide consume about 270 million tons of meat. By 2050, estimates place meat consumption at nearly 500 (470) million tons per year.²¹ The growth in the world's population, ongoing urbanization, and the rising middle class in China, among other nations, will increase the global demand for meat, eggs, and dairy. Even if it is possible for innovation in livestock management to increase production, so as to meet the growing demand, apart from the impact of climate change, analyzed in the next section, land and water resources will come under greater strain.

Livestock consume large amounts of calories in feed to produce the meat, dairy, and eggs we consume. For every

100 calories of grain fed to animals, humans obtain about 40 calories of milk, 22 of eggs, 12 of chicken, and 13 of beef.²²

A considerable portion of the arable land in use today goes to feeding and dealing with livestock. Estimates indicate that livestock production, directly or indirectly, accounts for 30 percent of the earth's usable surface land not covered by water and ice, or is bare rock.²³

With undrinkable sea water accounting for 97.5 percent of the earth's water and only 2.5 percent is fresh water, with 70 percent of this 2.5 percent trapped in glaciers and permanent snow,²⁴ the fresh water situation is most alarming. Today, raising livestock consumes about one quarter (23 percent) of the water's available freshwater. It takes 15,500 liters of water to produce one kilogram of beef. During its lifetime, on average, throughout the globe, a cow eats 1,300 kilograms of grain (wheat, oats, barley, corn) and 7,200 kilograms of roughages (pasture, dry hay).²⁵ The production of feed requires the withdrawal of significant amounts of fresh water. The exact amount of water used for feed production depends on a number of factors, including the region, feed composition, and the

origin of the feed ingredients. Besides water to grow fodder, each cow also needs water for drinking, servicing, and product processing.

In addition to using freshwater, the livestock industry damages the earth's increasingly scarce freshwater resources in other ways, by contributing, among other things, to water pollution. The major polluting agents include animal wastes, antibiotics and hormones, fertilizers, and pesticides used to spray feed crops. The runoff from these polluting agents disrupts rivers, lakes, and groundwater worldwide. Widespread overgrazing of livestock also upsets water cycles thereby decreasing the replenishment of above and below ground fresh water resources.²⁶

The bottom line with respect to livestock and the global land and fresh water problems: The planet must manage its food better for a massive number of people. We need to find more efficient ways to make proteins. At present, meat, dairy, and egg industries function as highly inefficient ways to produce proteins. One solution: plant-based animal products which likely produce protein more efficiently, more cheaply, and with less energy.

Proponents of lab-grown meat, for example, point to this product's ability to conserve resources. In comparison to conventionally produced meat in Europe, estimates indicate that cultured meat could reduce the need for water by 82 to 96 percent and land by 99 percent, depending on the specific product.²⁷ However, plant-based products may lack necessary nutrients found in traditional meat and eggs. Businesses must supplement their plant-based substitutes with vitamins, especially the B vitamins, and minerals, such as iron.

Environmental Impact

Alarmist environmentalists and many climate scientists view nasty future climate effects as our era's defining challenge. Unless significant changes are made with respect to fossil fuels, they foresee a global environmental catastrophe.

The voices of impending doom look to the reports of the United Nations Intergovernmental Panel On Climate Change, a worldwide committee of scientists charged with periodically assessing and summarizing the public scientific literature on the current state of the world's

climate science. In its latest synthesis report for policymakers, the panel stated that "[w]arming of the climate system is unequivocal..."²⁸ As the result of climate change, the "atmosphere and oceans have warmed, the amounts of snow and ice have diminished, and sea levels have risen."²⁹

The human impact on greenhouse gas emissions, specifically, the increase in the concentration of greenhouse gases, represents a key factor in climate change. Among other greenhouse gases, carbon dioxide serves as an essential element for earthly life. It enables green plants to convert sunlight into energy. However, at excessive levels, resulting, in part, from the burning of fossil fuels, particularly coal, as amplified by water vapor, it traps heat from the sun, causing the planet's surface to warm, at least the argument runs.

Looking to the future, the IPCC report noted that projected global mean temperature change, in 2081-2100 from the 1986-2005 mean, would likely range between 1.5 and 4.8 degrees Celsius, depending on the level of carbon dioxide emissions and the extent of future mitigation.³⁰ Thus, if current trends continue, according to the report, the world

probably will see major disruptions to natural ecosystems and human civilization, marked by food shortages from the difficulties in growing food, especially in the Southern hemisphere, a rapid rise in sea levels resulting in the flooding of major cities and island nations, precipitation changes, and extreme weather.³¹

Large-scale industrial livestock production adversely impacts the environment. It represents a major contributor, if not one of the greatest contributors, to greenhouse gas production.

Livestock activities worldwide produce in aggregate some twenty (18) percent of the non-natural global greenhouse gas emissions.³² Livestock production is responsible for more greenhouse gas emissions than the transportation sector, specifically, all the world's cars, trucks, buses, trains, ships, and planes combined. A considerable amount of fossil fuels are burned in the process of meat production, including the making and transport of feed, the rearing and slaughter of livestock, and the processing and shipment of meat. Cattle, among other ruminants, which eat grass, burp methane into the air as a byproduct of their digestion thereby contributing to

greenhouse gas emissions. The processing of animal waste, most of which is not recycled into fertilizer, releases methane and nitrous oxide into the atmosphere and also pollutes the groundwater. Methane and nitrous oxide are far more powerful greenhouse gases than carbon dioxide. Methane and nitrous oxide have, respectively, 21 and 296 times the global warming potential of carbon dioxide.³³ Including the emissions from land use, the global livestock industry accounts for 9 percent of the carbon dioxide derived from non-natural/human-related activities, 35-40 percent of the methane emissions, and 65 percent of nitrous-oxides,³⁴ with exact percentages varying by country and continent.

Proponents of plant-based or in vitro animal products see these substitutes as a significant, potential solution to climate change, which, as noted, is said to threaten the planet in the twenty-first century. They look to one study, where researchers estimated that lab-grown meat, in comparison to conventionally produced European meat, could, based on a theoretical, highly optimized model of in vitro meat production, cut overall energy use by 7 to 45 percent

and lower greenhouse gas emissions by 78 to 96 percent, depending on the type of meat.³⁵

Some experts dispute the more catastrophic predictions being made. Viewing it unlikely that we face an environmental disaster, they remain skeptical about the claims being made regarding the causes and effects of climate change. They foresee the warming likely to be limited and its impacts manageable.³⁶

Two points are not in dispute. Over the past century or so, the planet has warmed by a small amount, some 0.2 degrees Celsius during the last four decades, and sea levels have risen slightly. Humanity has had a role, albeit small, in these warming and sea level trends. For nearly 150 years, we have burned large amounts of fossil fuels and raised countless billions of livestock, however, with minimal impact on the climate.

Importantly, a slowdown in global warming has occurred over the past two decades or so. Although the IPCC report acknowledged this trend, it noted that "the globally averaged surface temperature exhibits substantial decadal and interannual variability,"³⁷ but the causes of the temperature variability are not fully understood. Computer

models were, however, unable to predict the long and continuing pause in the warming thereby placing in doubt the notion that climate science is settled and the future accuracy of the impact of global climate change.

Looking to the future, complex computer models, for example, those used in studies relied on by the IPCC, have a dismal record in predicting future temperatures and sea levels. They oversimplify the complexity of the earth's climate. It remains difficult to untangle the human impact on climate, including livestock production, from natural temperature variations. In other words, considerable natural, unforced variability exists with respect to climate trends. Also, the earth may be less sensitive to increasing greenhouse gas concentrations and the planet may not heat up as much as the IPCC predicts. Variations in solar radiation may impact on climate.

Recently, observation-based studies have found less climate sensitivity as the result of greenhouse gases than those using global computer models. One study estimates that the warming during the next seventy years, if carbon dioxide concentrations double, at a manageable 1.33 degrees Celsius, with a range of 1.05 to 1.80 degrees Celsius.³⁸

The for-profit businesses profiled in Chapter 3 through 7, offering plant-based and cultured animal product substitutes, strongest arguments focus on animal welfare and food safety. In response, producers have begun to raise animals with more compassion³⁹ and eliminate, or at least reduce, the use of antibiotics.⁴⁰ The widely trumpeted health and wellness as well as environmental impacts, which have public relations value, may not be grounded in reality. However, perception may be more important than reality. Public opinion sees climate change as a growing threat—we're going to cook the planet if we don't do something about greenhouse gas emissions. Responding to concerns about negative environmental consequences, traditional meat and dairy industries have sought to mitigate their climate impacts through various techniques, including reusing waste and biogas and increasing the amount of carbon sequestered on farm land. Also, a growing number of people believe that consuming animal products is insidious to human health and wellness. The bottom line: based on one or more of these four factors, animal welfare, human health and wellness,

resource scarcities, and climate change, for-profit businesses build their futures around plant-based and cultured animal products.

¹⁵ Multiple Risk Factor Intervention Trial Research Group, ''Multiple Risk Factor Intervention Trial: Risk Factor Changes and Mortality Results,'' *Journal of the American Medical Association* 248:12 (September 24, 1982): 1465-1477. The results of the Women's Health Initiative studies, which enrolled 49,000 women, ages 50 to 79, found that a low fat diet did not significantly reduce the risk of heart disease or cancer. Barbara V. Howard et al., ''Low-Fat Dietary Pattern and Risk of Cardiovascular Disease,'' *Journal of the American Medical Association* 295:6 (February 8, 2006): 655-666; Shirley A.A. Beresford et al., ''Low-Fat Dietary Pattern and Risk of Colorectal Cancer,'' *Journal of the American Medical Association* 295:6 (February 8, 2006): 643-

654; Ross L. Prentice et al., "Low-Fat Dietary Pattern and Risk of Invasive Breast Cancer," *Journal of the American Medical Association* 295:6 (February 8, 2006): 629-642; Ross L. Prentice et al., "Low-Fat Dietary Pattern and Cancer Incidence in the Women's Health Initiative Dietary Modification Randomized Controlled Trial," *Journal of the National Cancer Institute* 99:20 (October 17, 2007): 1534-1543. See also Glen D. Lawrence, "Dietary Fats and Health: Dietary Recommendations in the Context of Scientific Evidence," *Advanced Nutrition* 4:3 (May 2013): 294-302 and Gina Kolata, "Low-Fat Diet Does Not Cut Health Risks, Study Finds," *New York Times*, February 8, 2006, A1.

¹⁶ One of the meta-analytical papers, which looked at all the data from epidemiological (observational) studies, in which investigators profile subjects and then watch them over a period of time to observe health outcomes, concluded that saturated fat was not associated with an increased risk for heart disease or stroke. Patty W. Siri-Tarino et al., "Meta-analysis of prospective cohort studies evaluating the association of saturated fat with cardiovascular disease," *American Journal of Clinical Nutrition* 91:3 (March 2010): 535-546. A paper examining

all other evidence, including clinical trials, concluded that eating saturated fat is healthier than eating carbohydrates. Patty W. Siri-Tarino et al., "Saturated fat, carbohydrates, and cardiovascular disease," *American Journal of Clinical Nutrition* 91:3 (March 2010): 502-509. Another review of all studies of the low-fat diet concluded there is "no probable or convincing evidence" that a high level of fat in the diet causes coronary heart disease or cancer. Food and Agriculture Organization of the United Nations (FAO), *Fats and Fatty Acids in Human Nutrition: Report of an expert consultation 10-14 November 2008*, FAO Food and Nutrition Paper 91, 2010, 13. However, another meta-analysis of prospective studies supported the hypothesis that high consumption of red meat and processed meat was associated with an increased risk of colorectal cancer. Susanna C. Larsson and Alicja Wolk, "Meat consumption and risk of colorectal cancer: A meta-analysis of prospective studies," *International Journal of Cancer* 119:11 (December 1, 2006): 2657-2664.

3. Plant-Based Cheese Substitutes: Lyrical Foods

For years, companies have tried to develop alternatives to cheese, which people increasingly avoid for health reasons: it raises the bad cholesterol level; it has a high saturated fat content; they are lactose intolerant, that is, they are unable to digest lactose, a sugar found in milk; or they are allergic to milk, where the presence of milk proteins trigger an immune reaction. However, companies have found it difficult to develop perfect cheese substitutes with comparable taste and texture.

Vegans, those who abstain from consuming animal products, not only meat but also animal-derived substances, such as dairy products, face a forbidden food that taunts and tests their plant-based perseverance. That food is cheese. This is partly because cheese is so ubiquitous in food preparation, and for many, partly because of fondly remembered cheese-based childhood comfort foods.

The journey of Tal Ronnen, the chef behind Lyrical Foods' Kite Hill cheeses, profiled in this chapter, spans old-world cheesemaking, contemporary biotechnology, and venture capital funding. Culinary entrepreneurship as exemplified by Ronnen, combines environmental and vegan

ethics, a commitment to flavor, and a belief that technology and money can improve the world.

Non-Dairy Cheese Substitutes

For years, established companies have produced and sold vegan alternative, non-dairy cheeses, such as Daiya, Teese, and Tofutti.¹ Although intended as cheese replacements, they lack the texture, smell, and taste of dairy cheese, at least right out of the package. Best melted on food, these non-dairy cheeses remain a niche product.

These vegan cheese alternatives are typically made from soybeans, including tofu, soymilk, or soy protein isolate, but also from a variety of non-dairy ingredients, such as rice and almonds. As a result, they are skimpy in nutrients, such as calcium. Also, up to now, commercial nut-based cheeses often taste strongly nut-flavored, with a rather gritty texture. They do not resemble anything like an oozy brie.

Many dairy analogs are made with oils, such as coconut oil, making them high in fat, and highly processed ingredients, such as casein, which is extracted from dried

milk proteins. The use of casein makes them unsuitable for vegans, who eschew all animal products, including milk.

Lyrical Foods

Founded in 2011, Lyrical Foods, Inc. (Lyrical) produces non-dairy cheeses under the brand name Kite Hill Foods.² It has three co-founders: Tal Ronnen, a vegan chef; Stanford University biochemistry professor Patrick O. Brown, a molecular biologist and physician, and a member of both the Institute of Medicine and the National Academy of Sciences; and Monte Casino, a culinary instructor.

Ronnen's quest to make vegan cheeses worthy of a great chef began by visiting the cheese-making rooms at Le Cordon Blue Boston. There he met veteran instructor, Casino.

Traditional cheesemaking involves souring dairy milk and then adding renin, an enzyme, to thicken the protein and fat in the milk. Casino realized that nut milk has the same four components as dairy milk, namely sugar, protein, fat, and water, and thus should thicken similarly.

Ronnen's friend, Brown, had a project underway to develop nut milks for vegan cheesemaking. Connected by Ronnen to Brown, Casino started tinkering with samples of Brown's nut milks.

The trio took three years to develop cheeses out of an almond and macadamia nut milk base, together with a naturally-occurring enzyme found in plants and microbes, a bacteria started culture enhanced with a thickener, and salt, using the techniques of artisanal cheesemaking.

Traditional Cheesemaking

Traditional cheesemaking requires milk's protein, casein, and fat content to coagulate—curdle. Milk is first acidified by adding bacteria to convert the sugars into lactic acid requisite to form the softer curds characteristic of cheeses, such as cottage cheese. More rubbery, aged cheeses, such as cheddar, require added enzymes to achieve the desired taste and texture. For nearly all U.S. cheeses, coagulation is achieved with enzymes from one of two microbial sources. Today, only a small percentage, about 3 percent, of the cheese produced

in the United States use calf rennet, an enzyme derived from the stomach linings of very young calves.

Lyrical's Cheesemaking

Lyrical produces cheeses by inducing the enzymatic curdling of non-dairy milks. Unlike other non-dairy cheeses, the company does not use any artificial ingredients, starches or gums.

Lyrical perfected almond nut milk for its cheeses over many months of recipe testing and visits to some almond farms in California's San Joaquin Valley. After testing some twenty seven almond varieties, the team selected one to grind and triple-filter into silky white almond milk. Given the seasonal fluctuations in tree nuts' flavors and textures, the company custom blends each batch of almond nut milk for every cheese it makes. It then pasteurizes and inoculates the nut milk with a naturally occurring enzyme and a specially developed lactose-free culture. The firm has developed a technique that makes the nut milk proteins behave like those in dairy milk, compensating for a lack of milk protein, casein, and lactose so that the nut milk coagulates and forms a curd, which is then

concentrated and cultured similar to dairy cheese. It allows the mixture to coagulate slowly to let the curd fully develop the unique flavor and character that defines each of its cheeses. Eventually, employees distribute the curd by hand into traditional cheese molds where it is aged.³ Making its soft cheese products is a relatively long process as aging generally requires several days to a month or more.

Lyrical's Kite Hill Products

Lyrical's products are sold under the Kite Hill brand. Kite Hill's cheeses include several "soft fresh" varieties.⁴ These include: a soft and creamy mozzarella-style cheese and a semi-soft cheese crusted with paprika and fennel pollen. The soft and creamy cheese also comes in a chive, dill, and truffle flavor. The firm produces a ricotta cheese, smooth and moist, a plain and a chive cream cheese, and has several other soft cheeses in development.

Kite Hill's Distribution

Sold in puck-shaped packaging, Lyrical currently distributes its Kite Hill cheeses exclusively through Whole

Foods Market stores, initially in select locations in 2013. Beginning in 2014, more Whole Foods stores across the country offered Kite Hill cheeses. These cheeses are the first plant-based cheese Whole Foods sells in its cheese department, with other fine fromage, rather than in its regular dairy section. Lyrical also sells Kite Hill cheeses directly to selected restaurants.

Financing Lyrical Foods

Given the rich texture, mouthfeel, and flavor of its Kite Hill cheeses, Lyrical can sell to more than just vegan consumers. The size of the potential market has attracted funding from venture capital firms. In 2014, Lyrical secured an investment from Khosla Ventures. With these funds, Lyrical built a production facility in Haywood, California.⁵

Looking To The Future

Lyrical co-founder Patrick Brown sees a much bigger market than just cheese. He wants to give people the taste and nutritional benefits of foods from animals, particularly meat, without the negative health and

environmental impacts. To make “food for people who are comfortable eating meat and who want to continue eating meat,”⁶ Brown organized Impossible Foods, Inc. in 2011, which is examined in Chapter 6.

4. Plant-Based Egg Substitutes: Hampton Creek

For years, companies have tried to develop alternatives to eggs, mainly for health reasons. Four decades ago the American Heart Association, among other groups, discouraged people from eating eggs because it was thought that cholesterol-rich yolks would raise the risk of heart disease. Now, a reasonable consumption of eggs, such as one egg yolk per day, according to the Dietary Guidelines for Americans 2010, “does not result in increased blood cholesterol levels, nor does it increase the risk of cardiovascular disease in healthy people.”¹ Thus, today people avoid eggs for environmental, food safety, and animal welfare reasons, specifically, the traditional egg production system, which involves keeping hens packed into dirty cages and forcing them to produce eggs to the point of exhaustion. It is also inefficient compared to what might be done with plants.

It is a challenge, however, to find egg substitutes with comparable texture and flavor, while providing essential functions for cooking, such as the ability to bind foods and give them a satisfying mouthfeel. Current egg replacers, such as Ener-g Egg Replacer, which is vegan

and gluten free, as well as vegan (egg-free) mayonnaise brands, including Vegenaïse, Miso Mayo, and Egg Free Mayo, remain niche products. They have not achieved a high degree of household penetration.

This chapter profiles Hampton Creek's response to consumer demands for products, which are better for animal welfare and the environment. Hampton's lead product, its eggless Just Mayo condiment, has won shelf space at retailers, including Whole Foods Market and Wal-Mart. It is marketed as a mainstream brand: healthy, inexpensive, and good for everyone.

Hampton Creek

Hampton Creek Foods, Inc. (Hampton Creek), was co-founded in 2011, by Joshua (Josh) Tetrick, who currently serves as its chief executive officer, with Joshua (Josh) Balk. The firm wants to revolutionize the food system by moving the world from animal-based foods. It seeks to create by healthier, more sustainable, humanely produced, if not cheaper and tastier, plant-based alternatives.²

This desire to change the food system motivated Tetrick to start the company. Balk, Tetrick's long time

friend then working at The Humane Society of the United States told him about intensive commercial egg-laying facilities and inspired him to do better. Hearing about the carbon-intensive chicken raising process and the bad conditions in which most hens are kept opened Tetrick's eyes to how he might change the world through food. Seeking a plant-based, more affordable substitute for eggs, Hampton Creek was born, named after Balk's dog.³ The company has at its mission ``to decrease by 30 percent the number of egg-laying hens in battery cage facilities during the next five years [2013-2018]'' and ``end animal suffering in the egg industry.'' ⁴

The company began its quest to achieve its mission by sourcing plants worldwide. In building the firm, Tetrick quickly hired a protein chemist, a food scientist, a sales executive from Heinz, and a contestant from the television show, Top Chef.

Hampton Creek focuses on discovering vegetable proteins that replicate specific functions in both animal-based foods and in food preparation. It has examined some 7,000 plants and come up with eleven desirable proteins, seven of which are allowed in food by the U.S. Food and

Drug Administration.⁵ The company screened hundreds of varieties of yellow pea and used rapid prototyping technology to come up with pea properties that mimicked egg emulsion. For example, Canadian yellow pea (a type of split pea) protein emulsifies the oil and water in the firm's mayonnaise product.

To come up with better plant-based products, Hampton Creek relies more on computational science, not food science. The firm maintains an exhaustive database containing thousands of plant varieties, which correlates between their biochemical properties and functionalities, such as emulsion, coagulation, and aeration. The database facilitates the fast screening of plants from a molecular perspective. By classifying a plant's molecular properties and using the firm's predictive models, it can predict the kitchen use of a given plant species. As one journalist put it, "Food 2.0 companies [such as Hampton Creek] are using computational algorithms to analyze hundreds of thousands of plant species to find out what compounds can be stripped out and recombined to create what they say are more delicious and sustainable sources of protein."⁶ According to Tetrick, "Our vice president of data was head

of data analytics for Google Maps and YouTube, and our last seven hires have been data scientists. We can run our experiments in the cloud rather than always having to grind ingredients up and trying them out in a recipe.’’⁷

Hampton Creek’s Products

Hampton Creek uses plants, more specifically peas, to make its yellowish egg powder substitute, Beyond Eggs, which has properties similar to conventional chicken eggs. Its egg substitute is free of cholesterol, sugar, salt, allergens, and avian flu, and contains only a limited amount of saturated fat. Its technology platform enables the firm to produce a healthier product at a lower cost than traditional eggs. With conventional egg production costs rising, Beyond Eggs, its business-to-business product, presently costs about 18 percent less than real eggs.⁸ In short, it’s better for food manufacturers’ bottom line, not merely their animal welfare or environmental ethic.

Hampton Creek’s Distribution

Big food producers want to use a cheap, convincing egg substitute in their products. The company also thrives as a consumer brand in supermarkets.

In late 2013-early 2014, the company signed partnership agreements with six fortune 500 companies, including some of the world's largest food manufacturers and retailers.⁹ These firms use Beyond Eggs, a plant-based egg replacer, for baked goods and other food products, such as pasta.

Later in 2014, Hampton Creek signed a partnership agreement with the Compass Group, the world's largest foodservice company, to provide a replacement for its conventional chocolate chip cookies. The arrangement will enable Hampton Creek to bring its Just Cookies, a healthier cookie, to millions of customers. The plant-based product binds other ingredients like an egg in cookie dough. Each case of Just Cookies, consisting of 210 cookies, uses 2,000 fewer gallons of water, requires seven fewer square meters (about 70 square feet) of land, and contains 3,000 fewer milligrams (mg) of cholesterol or zero mg per cookie.¹⁰

Subsequently, in 2015, the Compass Group USA signed an even more significant distribution deal with Hampton

Creek.¹¹ Under the arrangement, Foodbuy, the Compass Group's procurement company, the largest foodservice and hospitality group purchasing company in North America, will add Just Mayo, along with Just Cookies, to the products it sells to institutional food providers, such as health care organizations, universities, and senior living facilities. Recognizing the importance of this partnership, Tetrick stated, "[W]e're tapping into this powerful, powerful infrastructure that determines what ends up on a lot of plates. This extends the reach of our products beyond anything we've done before."¹²

Hampton Creek's Just Mayo, an egg-free mayonnaise substitute, and its Just Cookies, an egg and milk-free cookie dough, found their way into supermarkets. The firm sells its flavored sandwich spreads under the name Just Mayo with a term describing the added flavors, such as Just Mayo Garlic. Just Cookies comes in four flavors: chocolate chip; sugar; oatmeal raisin; and peanut butter. It is working on developing a gooey egg-free mix, Just Scramble, designed to replicate scrambled eggs and other plant-based alternatives to pasta, ice cream, and salad dressings.

The prepared food counters at Whole Foods started using Just Mayo in September 2013.¹³ Quickly, Hampton Creek's Just mayo brand of eggless mayonnaise went on many Whole Food's shelves nationwide. Other supermarkets nationwide lined up in 2014, including Safeway, ShopRite, and Kroger as well as Target, Wal-Mart, DollarTree, and selected Costco Wholesale stores, to carry a shelf-stable non-refrigerated version of Just Mayo.¹⁴

Hampton's manufacturing partner produces Just Mayo. United Natural Foods, a distribution company, distributes the product to Whole Foods and other stores across the United States.

Financing Hampton Creek

Tetrick invested some \$37,000 of his own funds in the company in 2011. With its egg substitute widely used in mayonnaise and cookies, Hampton Creek easily raised capital from outside investors, who recognized what plant-based proteins could deliver.¹⁵ Initially, the firm obtained a \$2 million equity investment from Khosla Ventures LLC. Khosla provided \$500,000 in seed funding and subsequently invested \$1.5 million, which was used to expand corporate

headquarters and add additional employees. Also in 2011, Hampton Creek raised a \$1 million equity investment from Founders Fund, a venture capital firm founded by Peter Thiel and other former PayPal executives. Thiel seeks to back companies with big, ambitious plans. Two years later, in 2013, AME Cloud Ventures, the venture capital arm of Yahoo co-founder Jerry Yang, which focuses on technology-heavy companies, made a \$1 million equity investment.

Then in 2014, Hampton Creek garnered \$23 million in a Series B convertible preferred stock financing round. Horizon Ventures Ltd., which manages the investments of Li Ka-shing, the wealthiest man in Asia, focused on disruptive, technology-focused startups, led the round, pumping in \$15.5 million. Other investors included The Collaborative Fund, Tom Steyers' Eagle Cliff Partners LLC, and several individual investors, including Bill Gates, Google vice president Jessica Powell, and Scott Banister, a prominent angel investor. Khosla Ventures, an early investor, also participated in this round. Hampton Creek used these funds to accelerate its growth in North America, expand its operations in Asia, pursue strategic partnerships, and grow its team.¹⁶

In December 2014, the firm raised an additional \$90 million in a Series C financial round, bringing the company's total funding to nearly \$120 million. Horizons Ventures and Khosla Ventures co-led the round. New investors included Salesforce CEO Marc Benioff and Facebook co-founder Eduardo Saverin. The funds will go toward enhancing the firm's technology, such as better laboratory automation, general corporate expenses, and expansion in Western Europe and Asia.¹⁷

Awards Received

Hampton Creek received the Best of What's New 2013: 100 Innovations That Will Shape the Future Award by *Popular Science* for its plant-based egg substitute.¹⁸ The company was also named one of *Entrepreneur Magazine's* 100 Brilliant Companies in 2014, one of that magazine's 25 most innovative consumer and retail brands in 2014, and number 36 of CNBC's Top 50 Disruptors.¹⁹ *Inc.* magazine named Tetrick to its 35 under 35 list.²⁰

Success Leads To Litigation

In response to Hampton Creek's inroads in a traditional food category—mayonnaise—in October 2014

Unilever PLC, the maker of Hellmann's and Best Foods brands of mayonnaise, which controls 45 percent of the U.S. market, sued Hampton.²¹ Unilever accused Hampton of false advertising, specifically, for calling its eggless spread "mayo," and unfair competition. Marking one in a series of likely battles between established food companies, actually food conglomerates, facing competition from start-ups, luring consumers away from their traditional products, such as mayonnaise a \$2 billion per year market in the U.S., Unilever asserted that Just Mayo's label, which features a white egg cracked by a pea shoot, violates federal law governing trademarks and advertising. According to Unilever, the label gave consumers the false impression that the product contains eggs. Unilever also maintained that Just Mayo lacked testing to back up the claim that it beat Hellmann's in a taste test. Furthermore, Unilever claimed Just Mayo failed to meet the U.S. Food and Drug Administration's (FDA's) definition of mayonnaise, which must contain egg-yolk ingredients and a minimum percentage of oil, 65 percent by weight.²² In addition to seeking compensatory and punitive damages, Unilever demanded that Hampton Creek change the label of

its Just Mayo product, recall the product and promotional materials, and stop claiming superior tastes.

Recognizing that its lawsuit faced an uphill battle, Unilever dropped the suit,²³ after it became a public relations disaster. Hampton Creek never claimed its product was mayonnaise. Also, Unilever marketed products as mayonnaise that did not meet the FDA's definition. Raising the prospect that Unilever had ``unclean hands,`` Hampton Creek identified numerous changes to Hellmann's website in an attempt to rewrite history and characterize Unilever products as mayonnaise dressing.²⁴

From a policy perspective, the FDA's definition, more technically, the standard of identity, of mayonnaise reflects an outdated regulation from 1957, decades before vegan mayonnaise. It needs updating. As Tetrick stated: ``We've been going back and forth with them [the Food and Drug Administration] because the simple fact that this has happened speaks to the larger issue, which is we need for our regulatory framework to be more in line with the way we hope people are starting to eat.``²⁵

Looking To The Future

About one third of conventional chicken eggs wind up as ingredients in food products, such as mayonnaise and baked goods. Currently, there is a \$6 billion market for these egg ingredients globally.²⁶ It seems likely that Hampton Creek's plant-based egg products will disrupt at least the global egg ingredient industry, but not as quickly as its hopes. Its egg ingredient substitutes appeal to vegans, those with egg allergies, and those concerned about animal welfare, the environment, and food safety. In the future, it strives to appeal to those, worldwide, who want more affordable, better tasting, healthier egg ingredient products, such as mayonnaise, and even scrambled eggs. It is a scalable, viable, global solution.

However, Hampton Creek has encountered some speed bumps along the way. In early 2015, the company laid off about one fifth of its workforce, about a dozen of its 65 employees. Several more employees left voluntarily through a severance offer the firm extended. Shrouded in secrecy, allegedly some were dismissed for performance reasons and others for being negative. However, it was unusual for

layoffs to occur at a startup so soon after raising \$90 million in December 2014.²⁷

Undeterred, Tetrick, like Patrick Brown, has a bigger mission. They both want to create a new category of hyper efficient protein sources, among other food products, from plants. In implementing this goal, they want a better way to feed the world, with the best food accessible to average people. Their efforts have attracted not only savvy, big-name investors but also food manufacturers as well as health and environmentally-oriented consumers.

¹ U.S. Department of Agriculture and U.S. Department of Health and Human Services, Dietary Guidelines for Americans 2010, 7th ed., December 2010, 27. This guideline is in line with what research studies have shown. See, e.g., Frank B. Hu et al., "A Prospective Study of Egg Consumption and Risk of Cardiovascular Disease in Men and Women," *Journal of American Medical Association* 281:15 (April 21, 1999): 1387-1394 (consuming up to one egg daily did not raise the risk of heart disease or stroke in healthy adults) and Ying Rong et al., "Egg consumption and risk of coronary heart disease and stroke: dose-response meta-analysis of prospective cohort studies," *British Medical Journal* 2013;

346: e8539 doi: 10.1136/bmj.e8539. See also "Ask Well," *New York Times*, November 18, 2014, D4. Jang Yel Shin et al., "Egg consumption in relation to risk of cardiovascular disease and diabetes: a systematic review and meta-analysis," *American Journal of Clinical Nutrition* 98:1 (July 2013): 146-159, concluded by suggesting that egg consumption is not associated with the risk of cardiovascular disease and cardiac mortality in the general population.

5. Plant-Based Chicken and Beef Substitutes: Beyond Meat

For years companies have tried to develop alternatives to meat, which people increasingly avoid for health, environmental, food safety, and animal welfare reasons. The challenge is to find substitutes with comparable taste and texture.

Embarking on a quest to revolutionize eating with plant-based proteins that are better for consumers, animals, and the planet, Beyond Meat, analyzed in this chapter, seeks to produce and market a new kind of meat for the world. The firm strives to compete in the multibillion dollar beef and chicken industry and tackle a range of problems developed in Chapter 2, including improving human health and wellness, positively impacting the environment, addressing global resource constraints, and improving animal welfare. Rising to the difficult challenge, it provides consumers with hyper-realistic plant-based meat substitutes that provide the taste, texture, and nutritional benefits of chicken and beef.

Failed Soy Protein Substitutes

Mock meats from leading food processor companies, such as Kellogg Co. and Kraft Foods Group, Inc. are found in supermarket refrigerators and freezers. They are branded as Morningstar Farms Chik'n Nuggets, Turtle Island Foods Tofurky, Fried's Soyriso, Boca's All American Flame Grilled Meatless Burgers, and Nate's Classic Flavor Meatless Meatballs. These soy-based products use: pressed tofu, made by curdling fresh, hot soymilk with a coagulant; tempeh, a fermented soy product pressed into a cake; or textured soy protein, made from textured soy flour, textured soy protein, and spun soy fiber.¹

It is difficult, if not nearly impossible, to replicate the mixture of protein and fat found in meat. Heat from cooking alters the protein thereby creating meat's distinctive texture. Fat in meat provides flavor. Soy protein, however, is fat free. These substitutes lack the texture—the bit, chew, and juiciness of real meat. Not fibrous, they generally exhibit a spongy structure. Not resembling meat-like muscle food, they typically are also more expensive than real chicken or beef and thus, for several reasons, have not achieved a high degree of market

penetration. In addition, it is harder and harder to obtain soy from non-genetically modified organisms.

Beyond Meat

Founded in 2009, by Ethan Brown and Brent Taylor, Beyond Meat provides consumers with plant-based protein foods that remove animals from the production of chicken or beef without sacrificing taste, chew, or satisfaction. For example, its plant-based, chicken-free products look and taste like chicken. With a chewy, fibrous texture, they feel like chicken on taking a bite. They have a plumpness, what is called "mouthfeel," a kind of fattiness.²

Beyond Meat: Its Origins

After a successful career in the clean energy sector, specifically, the burgeoning field of fuel cells with Ballard Power Systems, a Canadian energy company, Brown realized that energy could only meet part of the climate change problem, at least as he saw it. With livestock generating so many greenhouse gas emissions, a basic question nagged him, why "continue to raise and eat animals in such staggering numbers if a delicious and

perfect plant-based replication of meat existed?''³ As a vegan, also concerned about animal welfare, he searched for a technology that could answer his question, taking plant-based proteins and realigning them to mimic the appearance and sensory experience of animal chicken and beef.

Without leaving his corporate position, Brown invested in several vegetarian restaurants specializing in mock meat sandwiches and salads made with soy-based tofu and seitan, a wheat gluten. Despite growing sales at these restaurants, he did not think that any of the items sold were good enough to eat without heavy seasoning or sauces.

In 2006, Brown began thinking seriously about creating animal protein with plants. Poring over the scientific literature, he discovered the work of Fu-hung Hsieh and his colleague, Harold Huff, a professor of food science and biological engineering and a senior research specialist, respectively, at the University of Missouri-Columbia.

Hsieh had focused on meat analogs, indistinguishable fakes, after writing his doctoral thesis on textured vegetable protein in the 1970s. He spent seven years at Quaker Oats, developing a patented technology to keep raisins in granola soft and moist. Because of his concern

about the global food supply, Hsieh returned to academia. With funding from the soy industry and the U.S. Department of Agriculture, Hsieh teamed up with Huff in an effort to produce a chicken-like product from soybeans.

For more than a decade, Hsieh and Huff toiled to devise the basic technique that Beyond Meat uses to produce its chicken- and beef-like products.⁴ In brief, the duo developed a high-moisture extrusion process, alternating high heat with high pressure, to reorganize plant proteins into a more animal-like alignment. Pressed through a large stainless steel extruder, the manipulated proteins ooze out as a kind of sludge.

After Brown sought out Hsieh and Huff and began a collaboration with them, the trio teamed up and entered into an informal agreement to try to turn plant-based chicken into a business.

With the production process solved, Brown approached the product from a marketing angle. To generate a distribution outlet, Brown met with a Whole Foods Market representative to pitch the chain on using the chicken-like product. Louise Liu, who oversaw Whole Foods product development in the Mid-Atlantic region, advised him she was

looking for an ingredient that could substitute for shredded chicken in the company's prepared foods. Realizing he had a product with wide appeal, Beyond Meat was born.

Beyond Meat: Its Management and Licensing

Brown, the firm's co-founder along with Brent Taylor, a former Kleiner Perkins employee, serves as its chief executive officer.

Beyond Meat licensed the two researchers' veggie chicken process. Under a 2010 licensing agreement, the University of Missouri-Columbia and the two scientists/investors receive royalties based on Beyond Meat's revenues. The university also owns a small equity stake in the firm.

Beyond Meat's Mission and Vision

Beyond Meat has a lofty corporate mission and vision. Its mission centers on creating mass market solutions perfecting and replacing animal protein with plant protein.⁵ As its vision, the company wants to reduce the world's consumption of animal meat by 25 percent by 2020.⁶ Beyond

Meat's factory in Columbia, Missouri can produce the equivalent of about 18 million chickens each year. Today, about 8.6 billion chickens are raised and slaughtered in the United States. Thus, Beyond Meat's 25/20 Vision appears unrealistic, absent other major entrants into the substitute animal meat arena.

Beyond Meat's Products

Beyond Meat's first product line, Chicken-Free Strips, embodies crafting plant-based proteins that replicate the sensory experiences of meat. Reflecting a blend of non-GMO (genetically modified organisms) soy and pea protein, a 3-ounce serving of Chicken-Free Strips delivers 20 grams of protein, but only 120 calories and 6 grams of carbohydrates. The strips are free of trans and saturated fats, cholesterol, dairy, egg, hormones, genetically modified organisms, antibiotics, meat, and gluten.⁷

The strips are made from: soy protein isolate, a protein isolated from soybean meal which has been dehulled and defatted; pea protein isolate; soy fiber; pea fiber; carrot fiber; and amaranth, a gluten-free grain. Other ingredients include dipotassium phosphate, a common source

of potassium, titanium dioxide, a naturally occurring mineral that helps the product look like chicken, and a vegan, plant-based chicken flavoring, consisting of maltodextrin, yeast extract, salt, natural flavoring, and sunflower oil.

Once measured, the dry ingredients are mixed with water, white vinegar, and expeller-pressed canola oil, which is free of saturated fat, to form a liquid paste. The mixers empty the resulting concoction into a cooker-extruder, a stainless steel machine, which heats and kneads the slurry under pressure to achieve the desired consistency. The product is then forced through specially made dies, which shape and cut the product. Four-inch long chicken-like strips emerge from the extruder, with the flavor and texture of the real thing.

The pre-cooked, pre-seasoned strips now come in three varieties: Southwest Style Strips, Grilled Strips, and Lightly Seasoned Strips.

Beyond Meat has also developed several beef-like products. Using pea, not soy, protein, its Beefy Crumbles and Feisty Crumbles substitute for ground beef. Consumers, food companies, restaurants, and school districts, among

others, can work these beef crumbles into tacos, lasagna, and sloppy joes.

In 2014, the firm unleashed The Beast Burger, a burger patty, and Beastly Sliders, both made from pea protein. They feature more iron and protein than beef, more calcium than milk, and more omegas than salmon. They are soy, gluten, and GMO free.

However, making fake steak is harder than making chicken strips or beef burgers. For example, people expect steak to look a bit red, from blood. More generally, it is hard to match the texture.

Financing Beyond Meat

With Beyond Meat's chicken-strips indistinguishable from the real thing, the firm experienced little difficulty in raising capital.⁸ Kleiner Perkins Canfield & Byers, one of the largest and most established venture capital firms, provided the initial funding, in a first-round, for Beyond Meat in 2011. The cash came in two tiers: the first, a proof-of-concept stage that allowed Brown to build a small production line in a former hospital and the second, when Whole Foods bought more of the chicken-like product.

The second funding round included Kleiner Perkins, Obvious Corporation, the tech incubator of Twitter co-founders, Christopher Isaac (Biz) Stone and Evan Williams, a former Twitter vice president, Jason Goldman, and a few others. Stone and Williams ultimately joined Beyond Meat's board of directors.

A third funding round included Bill Gates, Morgan Creek Capital, Closed Loop Capital, and Seth Goldman, the co-founder of Honest Tea.

New investors in a July 2014 Series D financing round included DNS Capital, representing the business interests of Jean (Gigi) Pritzker (Pucker) and Michael Pucker, Taiwan's Tsai family, through its family office, WTT Investment, and S2G. All of the existing investors also participated in this round.

The 2014 round enabled Beyond Meat to fund even greater innovative efforts to re-create meat from plants. The round also help the company expand consumer awareness and increase the company's manufacturing facility's capacity to meet the growing demand for its products.

Beyond Meat's Distribution

Beginning in 2012, Beyond Meat began providing its chicken-like strip product to Whole Foods Market for use in its prepared food sections, initially in the California Bay Area. Subsequently, in the spring of 2013, the firm made its chicken-like strips available to consumers in supermarkets, including not only Whole Foods, but also Publix, Safeway, Vons, and Ralphs, among others, throughout the United States.⁹ With the product available in these supermarkets' refrigerator cases with many other chicken substitutes, people can now purchase Beyond Meat's chicken-strips and heat it for themselves at home. Consumers can also buy the strips online through VeganEssentials.com and VeganStore.com.

Beginning in May 2013, Tropical Smoothie Café, a chain of more than 300 (336) stores that sells sandwiches and salads as well as smoothies, offered Beyond Meat's chicken-like product as an alternative to real chicken in its sandwiches and salads.¹⁰ In July 2013, the product became a permanent fixture on the chain's menu.

Awards Received

In 2014, *Fast Company* magazine named Beyond Meat as one of the world's most innovative companies in the food category.¹¹ It was included in the magazine's fifty most innovative firms in the world. Previously, PETA (People for the Ethical Treatment of Animals) named the firm as its company of the year in 2013.

Looking To The Future

Today, the suggested retail price for a 12-ounce package of Beyond Meat's chicken strips is less than a ready-to-eat equivalent, such as Perdue Short Cuts. However, big, vertically-integrated U.S. chicken producers, such as Tyson Foods and Perdue Farms, grow and process chickens for less than it currently costs Beyond Meat to produce its strips.

In the future, because it uses less feed, Beyond Meat may be able to compete with the leading U.S. chicken producers in a sustainable, profitable, scalable manner. A pound of its chicken-like strips needs only 1.1 pound of ingredients and two liters of water. Broilers require 7.5 pounds of dry feed and 30 liters of water to yield one pound of cooked, boneless chicken.¹² Feed costs account for

some 35 percent of the costs of chicken.¹³ If costs of feed, as well as energy and fertilizer rise over time, Beyond Meat will likely obtain a competitive cost advantage over traditional chicken producers and their products.

To scale the business, Brown must figure out how to market Beyond Meat's processed, not "natural," products and to whom. In addition to the quality of its products and their health, environmental, food safety, and animal welfare benefits, purchasers must derive a "great experience." At present, the company targets health-conscious carnivores, who want to reduce their meat consumption, not just vegans or vegetarians. It hopes that supermarkets will carry its chicken and beef products in the respective meat aisles, not in the plant-based protein section.

However, its chicken-like strips currently are frozen at the factory. As a result, they suffer from many of the texture issues that frozen meat faces when thawed, namely, graininess and chewiness. At present, it is unclear whether Brown can ship the product refrigerated rather than frozen.

Also, for purists, soy in its chicken-like strips represents a possible contentious ingredient because of possible health risks and a negative connection to large farm, industrial agriculture. Beyond an allergy or food intolerance to soy, women with current or past breast cancer may face potential tumor growth when taking soy products.¹⁴

At the end of the day, Brown believes, however, that the public will accept Beyond Meat's innovations as they have adapted to past technology revolutions. "Once, we had the horse-drawn carriage, and then we had the horseless carriage, and then we had the automobile," Brown stated. He continued, "I'm firmly convinced we're going to go from beef and chicken products that are animal in origin to those made from plants—and at some point in the future you'll walk down the aisle of the supermarket and ask for beef and chicken, and like the automobile has no relationship to the horse, what you get will have nothing to do with animals."¹⁵

6. Plant-Based Beef Substitutes: Impossible Foods

The chapter examines the efforts of Patrick Brown to go beyond cheeses, examined in Chapter 3, and manipulate plant material to create a meat facsimile, with the right taste, mouthfeel, and texture. With his proof-of-concept, which mimics meat from vegetable sources, Brown attracted one of the largest amounts of venture capital funding of any of the firms discussed in this book, apart from Hampton Creek. Despite his audacious efforts, little is publicly known about Brown's company, Impossible Foods.

Brown, a vegan, sees a much bigger market for plant-based animal product substitutes than just the Kite Hill cheeses sold by Lyrical Foods. Motivated mainly by environmental concerns and a desire to create more sustainable food sources, he wants to put a significant dent in our hunger for beef and thus reduce, and if not eventually eliminate, the animal farming industry.¹

After two years of background research, Brown's quest led him to organize Impossible Foods, Inc. in 2011. The company has as its mission "to give people the great taste and nutritional benefits of foods that come from animals without the negative health and environmental impact."²

The Science Behind Plant-Based Beef

In his quest to develop a plant-based meat, Brown, given his scientific background, sought to understand the molecular reasons why beef tastes like beef.³ To replicate the taste of meat, he needed to understand and create plant ``blood.``

Heme, a molecule in hemoglobin and myoglobin, two key proteins, found not only in cows' blood, among other animals, but also in plants, makes blood red.⁴ Brown found that heme is responsible for beef's distinctive color. When exposed to amino acids and sugars, it unlocks flavors. As a major carrier of iron, its presence likely also gives cooked beef its distinctive taste.

To solve the texture riddle, Brown and his team identified those plant compounds requisite to creating fat, connective tissue, and muscle. These compounds give the ``meat`` the consistency of real beef. Because researchers can control the placement of fat in a piece of meat, the uniform distribution of fat yields perfectly marbled beef.

The result: as his proof-of-concept Brown created a hamburger that looks and smells like a cooked ground beef burger. Although its taste and texture are not perfect, at present, it has the appropriate mouthfeel.⁵ Its protein content is higher than a conventional burger. It is free of antibiotics, hormones, and cholesterol.

Financing Impossible Foods

Based on Brown's research and the quality of Impossible Foods' meat-like product, thus far developed, in 2014 the company gained some \$75 million in capital from Khosla Ventures, Horizon Ventures, Google Ventures, the independent venture capital arm of Google Inc., which provides funding for technology companies, and Bill Gates.⁶ Most of the funds went into creating the company's manufacturing facility.

Looking To The Future

Even with its proof-of-concept, Impossible Foods faces a major hurdle. To market its beef product, the firm must substantially reduce the \$20 cost of producing a small patty. It is unclear whether the company can devise

cheaper manufacturing processes and decrease the cost of its raw materials, even if its scale increases. At present, Brown's burger requires large quantities of five plant species. However, Brown's quest for excellent tasting, healthy "meat," which is best for the planet, and affordable, continues.

7. Bioengineered Meat and Leather: Modern Meadow

Through stem cells, cell culture, and tissue engineering, academic scientific researchers have created lab-grown meat by biopsying and isolating the desired cells from living animals, growing these cells, and producing a beef surrogate made of the same real meat is composed of. They grow this test-tube engineered meat in vitro, that is, outside of an animal's body.

One firm, Modern Meadow, profiled in this chapter, plans to apply biofabrication technology first to create leather from animal skin cells. With the meat we eat consisting of muscle tissue from animals, such as cows, working with molecular technology experts, the company ultimately hopes to create cultured meats from muscle cells.

Biofabrication Meat Academic Pioneers

In 2013, a team of Dutch researchers led by Mark J. Post, M.D., Ph.D., successfully unveiled the first lab-grown burger from cow stem cells.

Post, a professor in the physiology department at Maastricht University in the Netherlands, a vascular

biologist and a surgeon, with a doctorate in pulmonary pharmacology,¹ had shifted part of his research from biomedicine, more specifically, creating arteries to replace and repair those in diseased human hearts, to develop lab-grown meat.

In August 2013, Post demonstrated the world's first lab-grown hamburger for the press.² At a news conference, which was broadcast live on the web, a food writer and a food scientist ate the five-ounce burger that was grown from stem cells taken from two cows. One taster positively indicated, "The mouthfeel is like meat. I miss the fat, there's a leanness to it, but the general bite feels like a hamburger."³ The other was more guarded in his assessment.

To produce the cultured beef burger, Post's team first biopsied adult stem cells from a donor cow.⁴ After extracting and isolating the muscle stem cells, the team incubated these cells in a growth mixture, consisting of amino acids, sugars, minerals, and fetal bovine serum, to supply the nutrients blood would ordinarily provide. The last ingredient, a clear liquid separated from unborn calf embryos' clotted blood, represented the by-product of the slaughter of pregnant cattle. As the muscle cells

multiplied, they grew together, forming muscle tissue. To facilitate the multiplying and fusing, researchers attached muscle cells to specially prepared cylindrical scaffolds and used tension to simulate muscle maturation.

The August 2013 hamburger that Post presented and had cooked and sampled used some 20,000 muscle strips. To ensure that the nutrient-rich growth medium reached all muscle cells, the team produced the lab-grown muscle tissue in very small pieces. In making the burger, Post also added beet juice, caramel, and saffron to improve its color and flavor, and breadcrumbs and egg power to obtain a texture more similar to ground beef.

The test demonstrated the technology's proof-of-concept. Establishing the technical feasibility of using tissue engineering to create cultured beef was, however, exceedingly expensive. It cost about \$325,000, paid for by Sergey Brin, Google's co-founder. Because of its price tag, this product is not consumer-ready.

In addition to the need to generally reduce costs and increase efficiency,⁵ to become commercially viable and meet scale up demands, Post must develop a cheap, effective substitute for expensive fetal bovine serum, the growth

promoting blood-derived product. Besides being expensive, some \$500 for 500 milliliters and not animal friendly, different batches of serum-based media have variable impacts on cell growth, which renders it unacceptable for commercial uses.

If a business wants to exclude living farm animals from the biofabrication process, apart from extracting cells, lab-grown meat would need a non-animal-based growth medium. A plant-based growth medium, such as algae, should be less expensive than fetal bovine serum; however, it is unclear whether a plant-based medium would cause allergic reactions in some consumers.

Post also sees the need to work on the cultured meat's fat content and its protein composition.⁶ As noted, Post confined the technology to small pieces of muscle tissue. Post's lab-grown meat lacks the blood vessels needed to deliver oxygen and nutrients into the tissue to keep it alive and make thick muscle tissue for certain meat cuts, such as steak. It is uncertain whether researchers can figure out a way to somehow synthesize something like blood vessels so as to nourish cells at the center of the muscle tissue as it grows thicker.

In short, the product of Post's methodology is too expensive at present. Even if costs fall substantially, the technology may be too complex to be commercially viable.

Modern Meadow

Modern Meadow develops cultured leather and meat from animal stem cells. It uses biofabrication, a tissue-engineering technology to grow leather from skin cells and meat from muscle cells.

Modern Meadow: Its Origins

A father-son team, Gabor and Andras Forgacs, founded Modern Meadow. Gabor Forgacs, Ph.D., a theoretical physicist who turned to developmental biology, holds an endowed chair and heads the University of Missouri-Columbia's biophysics laboratory and serves as the executive and scientific director of Clarkson University's Innovation Center.

The father's scientific team invented and the son helped commercialize bioprinting, a technology facilitating building tissues based on 3D computer-controlled cell delivery.⁷ In 2007, they co-founded Organovo, now a publicly-held regenerative medicine company, which applies bioprinting technology to medical applications.⁸ The company bioengineers human tissues for use by pharmaceutical companies in drug development and testing, among other medical applications. As an elusive goal, Organovo's human tissues could ultimately serve as replacement organs, such as a kidney, for patients needing a transplant. If bioprinted organs were made from patients' own cells, they would not be subject to rejection by immune systems. These organs could also be produced on demand.

After their success with human tissues, the duo started getting a question: If you can grow human body components, can you grow animal products, such as meat and leather? However, with a medical focus, Organovo's technology centered on engineering high-fidelity human tissues. To take bioengineering technology beyond regenerative medicine, the father-son team founded a new

company, Modern Meadow, after Organovo brought in a new management team in 2011 and formulated plans to go public.

Modern Meadow: Its Founding And Focus On Leather

In September 2011, Andras Forgacs co-founded Modern Meadow with his father, Gabor, and two of Gabor's university colleagues, Françoise Marga and Karoly Jakab. In January 2012, Andras became its chief executive officer, with Gabor serving as its chief scientific officer. The firm plans to use Gabor's research to create leather goods and cultured meat for the consumer market.⁹

A big market exists for novel consumer biomaterials, such as leather. For example, a \$63 billion annual global market exists for leather products.¹⁰

The father-son duo began to reimagine cultured leather to be used to make consumer goods, such as shoes, apparel, handbags, and luggage. Growing leather involves one type of cell, the basic unit of life, to make skin, and is largely two-dimensional. Leather, even meat, is simpler to produce than functioning human parts, Organovo's focus. No need exists to be as exacting or worry about compatibility.

Thus, through biofabrication, Gabor's technology, cells can grow biological products, such as leather.

Modern Meadow's Technology

The biofabrication process for leather is straightforward, with skin cells having a simpler molecular structure than muscle cells for meat. Through a biopsy, Modern Meadow begins by taking stem cells from an adult donor animal, such as a cow which leads a normal life. For leather, it then isolates the skin cells and multiplies them in a bioreactor's cell culture, using fetal bovine serum, as noted, a fluid derived from calves' embryos. After centrifuging the mixture to eliminate the growth medium from the skin cells, it lumps the cells together to create aggregated spheres of cells. The firm coaxes the cells to produce collagen, material between the cells, which serves as a natural connective tissue. Collagen gives the cells structural support as it would do in an animal. In leather, collagen serves as the product's main building block. The company then takes the skin cells and the collagen, and spreads them out to form sheets, layering the thin sheets on top of one another to form thicker

sheets in a process called bioassembly. The sheets are then left to mature and thicken. Dispensing with chemical intensive, early tanning steps designed to remove animal hair and flesh, through a shorter, less toxic chemical tanning process, the firm creates real leather from the multilayered skin cells.

The leather end product of the biofabrication process has all the characteristics of genuine leather. It is made from the same cells. Furthermore, there is no hair to remove or any waste from irregular natural hides. The cultured leather is free from imperfections, such as scars or damage from insects or barbed wire. The firm can fine-tune its leather for desirable qualities, such as thickness, softness, durability, or elasticity, so as to improve on it.

Marketing Modern Meadow's Leather

From a marketing standpoint, leather represents a "gateway product" on which to build Modern Meadow and the biofabrication industry. According to Andras Forgacs, "It [leather] is less...polarizing for consumers and regulators. Until biofabrication is better understood, it is clear

that, initially at least, more people would be willing to wear novel materials than would be willing to eat novel foods, no matter how delicious.’’¹¹ He also noted that anecdotally only about ‘‘40 percent of people would be willing to try cultured meat. There’s much less controversy about using leather that doesn’t involve killing animals.’’¹² Beyond public perceptions, lab-grown leather would not require approval by the U.S. Food and Drug Administration (FDA).

The U.S. Department of Agriculture is responsible for the safety of meat, poultry, and processed egg products, with the FDA responsible for all other foods. The FDA’s treatment of cloned animals provides insight into how it might handle in vitro meat. In 2008, the FDA announced that humans could safely consume meat from cloned animals, specifically cattle, pigs, and goats, any products derived from such animals, and their offspring.¹³ In reaching this conclusion, the FDA considered various factors, such as the use of clones primarily for breeding and the nature of these clones compared to genetically-engineered animals. The U.S. Department of Agriculture regulates the safety of meat in the United States, focusing on preslaughter

inspections of animals, including requiring sterile and sanitary conditions for any surface or tool coming in contact with meat, the use of safe cleaning products to ensure sanitary conditions, and a standard of cleanliness for those working with meat.¹⁴ In short, the Agriculture Department, which strives to ensure that meat products do not become adulterated as a result of unsanitary processing and handling, would likely assume primary responsibility in ensuring the safety of in vitro meat.

Given the absence of regulatory approval for leather, Modern Meadow hopes to have full-scale leather production facility up and running in five years (2012 to 2017). The regulatory process for in vitro meat could take upwards of ten years (2012 to 2022).

Initially, the company will introduce its leather at the high-end of the leather price spectrum, some \$1,000 per square meter (or about \$100 per square foot). When production scales up, its leather will become more affordable, at least that is the firm's not unreasonable expectation.

Financing Modern Meadow

Building on the practicality of its biofabrication technology, Modern Meadow obtained various grants and received funds from investors, including high profile venture capitalists. In 2012, the firm received a \$92,000 (\$92,488) Small Business Innovation Research (SBIR) Phase One grant from the U.S. Department of Agriculture for its bioengineered meat.¹⁵ The next year, it received a \$150,000 (\$149,994) U.S. National Science Foundation SBIR Phase One grant for its Tissue Engineered Sustainable Leather.¹⁶

Non-governmental grants also funded the firm. In August 2012, through Breakout Labs, Peter Thiel, a prominent venture capitalist, PayPal co-founder, and an early Facebook investor, backed Modern Meadow with a \$350,000 grant.¹⁷ Breakout Labs serves as the Thiel Foundation's initiative focused on assisting what it regards as breakthrough science and technology companies. It gives grants to early stage research projects deemed unsuitable for traditional funding sources because of their radical nature or too speculative to interest venture capitalists. With the help from these funds, Andras Forgacs set up an office at the Singularity University Labs Idea Center on NASA's Silicon Valley research park campus.

Previously in 2012, Singularity University, a technology advancement and education organization, included Modern Meadow in its inaugural synthetic biology accelerator program, SynBio Startup Launchpad. In addition to a \$60,000 grant, Modern Meadow founders underwent four months of comprehensive, customized mentoring and education to help bring their ideas to market.¹⁸

After obtaining nearly \$1.5 (\$1.4) million in investments from angel investors and seed venture capital funds, including Sequoia Capital, Artis Ventures, and Iconiq Capital, in June 2014, the company raised \$10 million in a Series A convertible preferred stock funding round led by Horizons Ventures.¹⁹ The firm used the funds to accelerate its research and development and open an expanded research headquarters in Brooklyn, New York.

Award Received

In 2013, *Entrepreneur* magazine named Modern Meadow as one of its 100 brilliant companies. Specifically, the magazine designated the firm as “leading the future of farming.”²⁰

Looking To The Future

Modern Meadow appears wise to focus its efforts initially on leather, not meat. Beyond the regulatory uncertainties and delays with respect to biofabricated meat, a challenge exists in persuading consumers to buy cultured meat. Unlike Brown's Impossible Foods' beef, at present Modern Meadow's meat lacks blood and fat content. Apart from palatability questions, including appearance, taste, texture, and aroma, the company may face public opposition to lab-made meat. Simply put: it's the 'yuck' factor.²¹

However, people daily eat cultured food products, such as cheese and yogurt. Also, if the price of real meat rises because the supply cannot match the growing demand, necessity may cause the opposition to decline. The firm may also sell 'supermeats,' which would be enhanced with items, such as omega-3, not found in the real thing.

Even overcoming the consumer acceptance hurdle, Modern Meadow faces three further obstacles in its efforts to commercialize bioengineered meat production. First,

despite the grants and investments the firm has obtained to date, some estimates indicate that the commercialization of cultured meat production by one firm may require an investment of upwards of \$160 million.²²

Second, to reduce costs and gain uniformity, Modern Meadow would want to grow muscle cells and its meat without the aid of an animal-derived liquid culture medium, such as fetal bovine serum.

Third, producing biofabricated meat on a large, efficient scale raises additional questions. Growing meat in giant bioreactors, expensive to design, build, and maintain, may raise energy issues. However, only small amounts of electricity, perhaps from solar panels, may be required to regulate bioreactors' temperatures.

Cultured meat production requires some type of exercise to stimulate muscle growth in what will become meat. It is uncertain whether just a minor electric current can mimic the effects of natural bovine movements.²³ Thus, exercising muscle fibers with electricity may not be energy efficient. However, despite these cost considerations, cultured meat will require less water, land, and energy inputs, per pound, than traditional meat.

III. Replacing Conventional and Substitute Foods

8. All-In-One Liquid Meal Replacement: Rosa Labs

Going beyond salt, cheese, egg, and meat substitutes, some want to reinvent food. They seek to change the world's relationship with food by developing a total food replacement product, something designed and optimized by humans, which would transform the way we live.

A market may exist for all-in-one meal replacements, healthy substitutes that are easy and cheap. Fresh organic food is expensive. Shopping for food and cooking meals from scratch is time consuming.

Through his Soylent product, Robert (Rob) Rhinehart set out to develop and commercialize a convenient, relatively inexpensive, but efficient source of nutrition and energy for every human being. He designed the product for those who do not have the means to eat well, for anyone struggling with food allergies, heartburn, acid reflux, or digestive problems, or having trouble controlling their weight or their bad cholesterol level. In his view, it would also help protect the environment by reducing, if not eliminating, much of the waste and harm resulting from

agricultural and livestock production as well as food-related trash.¹

Someday, Rhinehart hopes that Soylent could be sold everywhere, even in convenience stores. He wants it to compete against cheap, but unhealthy, snack, junk, and fast foods, linked to obesity, diabetes, and malnutrition, currently found all around us in the United States. This chapter explores his quest to have many people live on Soylent for most of their meals.

Other Liquid Food Replacements

Meal replacement products are not new. When a hospital patient is too sick to eat, for decades, he or she received groundup food in feeding tubes. Companies, such as Abbott Nutrition, got into the commercial meal replacement game with Ensure. From the 1960s through the 1990s, the diet crowd turned to liquid meal replacements, which made it easy for them to quantify their calorie consumption and lose weight. It became the era of Unilever's SlimFast. More recently, aspiring bodybuilders drink Muscle Milk, a protein shake to build brawn.²

In short, there are many meal replacement liquid shakes on the market, serving various needs. However, these replacement products can be more expensive than traditional food and may not provide a nutritious diet. Today, Rosa Labs' Soylent aims to market to those craving a healthy, efficient alternative for most of their meals, not dieters, the elderly, or those wanting to build muscle.

Soylent: Its Origins

In a blog, "How I Stopped Eating Food,"³ Rhinehart described his reasons for and how he created a food substitute that provides, according to him, the body with everything it needs for healthy living. Noting the inefficiencies in the existing food system, he stated, "Food is the fossil fuel of human energy. It is an enormous market full of waste, regulation, and biased allocations with serious geo-political implications. And we're deeply dependent on it. In some countries people are dying of obesity, others of starvation. In my own life I resented the time, money, and effort the purchase, preparation, consumption, and clean-up of food was consuming [some two hours a day]...I don't want to lose

weight. I want to maintain it and spend less energy getting energy.” He continued, “I hypothesized that body doesn’t need the food itself, merely the chemicals and elements it contains. So, I resolved to embark on an experiment... I just want to be in good health and spend as little time and money on food as possible.”⁴ He further noted:

“I don’t think we need fruits and veggies, though — we need vitamins and minerals. We need carbs, not bread. Amino acids, not milk. It’s still fine to eat these whenever you want, but not everyone can afford them or has the desire to eat them. Food should be optimised and personalised. If Soylent was as cheap and easy to obtain as a cup of coffee, I think people would be much healthier and healthcare costs would be lower.”⁵

Seemingly, an impossibly busy man, wanting to live as cheaply as possible and seeing conventional food as an inefficient way to survive, in his words, a “system that’s too complex and too expensive and too fragile,”⁶ he decided to create a new, nutritionally-complete product from scratch. Pouring over textbooks, open access scientific journals, dietary guidelines, and getting some basic biochemistry lessons from a roommate, with a biology background, Rhinehart, an electrical engineer, came up with

a liquid meal replacement, which he named Soylent, after the 1973 dystopian science fiction movie, ``Soylent Green.''

Striving to save nearly all the time and effort, as well as part of the money, which usually went into shopping and preparing food, and cleaning up, he subsisted on his concoction, first for thirty, then sixty days,⁷ without eating food in a conventional sense. Although he started eating real food thereafter, what he calls ``recreational meals,''⁸ Rinehart gets some ninety (92) percent of his meals from Soylent, with only one or two conventional meals weekly.

During his two month experiment phase, Rhinehart replaced food entirely with a liquid shake, thick, doughy, odorless, yellowish-beige in color with all the protein, fat, fiber, carbohydrates, and micronutrients, in various portions humans need, allegedly for a balanced diet, but with one third of the calories. He based his recipe on the daily intake recommendations of the Institute of Medicine. There are no meats, fruits, or vegetables, real or substitutional, or any toxins, carcinogens, hormones, or preservatives.

Soylent: The Product

Allegedly, Soylent provides all the essential materials we need from food, but not any of the "extra stuff," perhaps enabling the body to operate more efficiently. Filling humans' complete nutritional needs, the product contains a number of ingredients.⁹ Lipids come from canola oil; carbohydrates from maltodextrin (commonly derived from corn) and oat flour; protein from rice. In Soylent 1.2, Rhinehart replaced the Omega-3 fatty acids from fish oil with algae oil, cultivated in large fermentation tanks, thereby making the product suitable for vegans.¹⁰ However, it contains genetically modified organism ingredients, soy, and gluten. Doses of minerals include iron, potassium, magnesium, calcium, and zinc.¹¹ To mask the taste of various minerals and vitamins, it contains a small amount of sucralose. He also added some non-essentials, such as antioxidants and probiotics. The only ingredients recognizable as food are canola oil for fatty acids and table salt for sodium chloride.

Soylent and the Food and Drug Administration

Unless a dietary supplement introduces a new nutritional ingredient, the U.S. Food and Drug Administration (FDA) need not to give its approval for safety or effectiveness before the product goes on the market.¹² By using previously available ingredients each of which the FDA recognized as safe and which undergo no chemical changes when blended together with water, Soylent, as a traditional dietary supplement, is considered legal. It is not subject to FDA approval or oversight. Thus, the product avoided the FDA's regulatory grasp and its expensive, burdensome, time-consuming testing process. Furthermore, no disclosures need be made to the FDA or consumers of any information about the safety or the purported benefits of Soylent.

Rhinehart's Observations After Existing On Soylent For Thirty Days

In addition to saving him time and money, while yearning for the productivity benefits of being healthy, Rhinehart saw the positive, qualitative results after thirty days of subsisting only on Soylent. He noted:

I feel like a six million dollar man. My physique has noticeably improved, my skin is

clearer, my teeth whiter, my hair thicker and my dandruff gone...I have more energy than I know what to do with.

...

My mental performance is also higher... My working memory is noticeably better... My awareness is higher... My reflexes are improved... I sleep better, wake up more refreshed and alert and never feel drowsy during the day.¹³

However, these are subjective observations. He also transitioned from a diet often devoid of healthy foods to one rich in vitamins and minerals and began exercising. In addition to finding the taste "very good" and not tiring,¹⁴ Rhinehart explained his reasoning why many people would in the future relegate themselves to a single food source as follows:

Not having to worry about food is fantastic. No groceries, dishes, deciding what to eat, no endless conversations weighing the relative merits of gluten-free, keto, paleo, or vegan. Power and water bills are lower. I save hours a day and hundreds of dollars a month... I feel liberated from a crushing amount of repetitive drudgery. Soylent might also be good for people having trouble managing their weight. I find it very easy to lose and gain precise amounts of weight by varying the proportions in my drink.¹⁵

Rhinehart candidly noted some drawbacks. Although it has a one-year shelf life, Soylent does not keep long after mixing with water. Users must refrigerate the mixture and

consume it within 48 hours. People who enjoy eating food will not like the idea of a liquid meal replacement.

Three months after his thirty-day blog post, ``How I Stopped Eating Food,’’ he realized that his mixture had the makings of a for-profit company. Rhinehart and his two roommates put aside their wireless networking tech startup project to make inexpensive cell phone towers and went into the synthetic food business. They organized Rosa Labs, LLC in May 2013.

Financing Rosa Labs

To attract funding for Rosa Labs, Rhinehart and his two co-founders launched a crowdfunding campaign in May 2013 with the goal of raising \$100,000, which they hoped to raise in one month. When they opened up to donations, they met their financial objective in two hours. The crowdfunding campaign, which ended in May 2014, raised more than \$3 million dollars, indicating an extensive market for backers of fuss-free food.

Even before the end of the crowdfunding campaign, in October 2013, the firm closed on a \$1.5 million seed funding round.¹⁶ Investors in this round included

Andreessen Horowitz and Lerer Ventures. Other backers included Initialized Capital and Hydrazine Capital. Start Fund and Y Combinator, the later entity a seed incubator and accelerator, which provided funds for Rhinehart's abandoned wireless network startup, also own part of Rosa Labs.

The company used the seed round funds to help bring its manufacturing in-house, thereby lowering its costs. Funds also went to product development, including hiring a culinary director to work on the product's taste and mouthfeel. Rhinehart also relocated Rosa Labs to Los Angeles to reduce the previous costs of operating in San Francisco.

In January 2015, Rosa Labs received \$20 million in a Series A funding round, led by Andreessen Horowitz.¹⁷ Other participating investors included Lerer Ventures.

Rosa Labs Ships Soylent

In May 2014, Rosa Labs shipped the first 30,000 units of commercially-made Soylent to customers across the United

States.¹⁸ These shipments went to the firm's initial crowdfunding backers.

The commercial version of Soylent comes in a powder form, with a day's supply in a plastic pouch containing 1,530 calories of beige powder. Initially, an oil preparation, 480 calories, came in a separate bottle. Today, Soylent uses a blend of powdered oils, sunflower, flaxseed, and algae, as the source of necessary fats. To prepare a meal, a purchaser scoops the powder into a plastic pitcher, which comes with the powder, adds water, and shakes it up, producing a thick, beige liquid, which is yeastly, grainy, somewhat sweet, even dessert-like. The pitcher stores an entire day's worth of the liquid at once.

Award Received

In 2015, *Forbes* magazine selected Rhinehart as one of its 30 under 30 in the food and drink category.¹⁹

Looking To The Future

It is uncertain at present whether Soylent represents the end of conventional or substitute food as we know it.

The geek dream of a post-food future not only has advantages, but also question marks and negatives.

On the plus side, Soylent is much cheaper than other liquid meal replacement products.²⁰ At \$85 (as a one time purchase) for seven bags, with one bag providing more than three meals or \$70 (as a monthly subscription) for a week's supply, it can also compete pricewise against the ubiquitous snack, junk, and fast foods. Even lower prices exist for two week and one month supplies. It is much healthier than these food sources. It is easy to use, nutrient-rich, and hunger-curbing. With its lack of "real" food sources, except canola oil, salt, oat flour, and rice protein, Soylent should scale well in manufacturing and distribution, unlike fresh fruits and vegetables, which are incompatible with scale. Besides being cheaper, it is customizable for those requiring considerable protein or not needing as many calories.

However, mainstream physicians and dietitians remain skeptical about Soylent. We do not know everything that goes into optimally health diet, beyond just surviving. No one understands the long-term implications of switching their diet exclusively or mostly to Soylent. One

registered dietitian and an assistant professor of medicine warned that a strong possibility exists that a Soylent diet could miss something critically important from the essential nutrients in food. Humans may need the substances found in “real” foods, most notably phytochemicals, which come from the plants. These compounds seemingly provide health benefits, but we do not know for certain. Lycopene, which makes tomatoes red, may lower prostate cancer rates. Flavonoid compounds, which make blueberries blue, are linked to lower diabetes rates. Her bottom line: “I would not promote this type of diet to the general public, as there are many ways it can go wrong, especially if consumed long-term.”²¹

In short, it’s difficult to itemize a final list of what humans need for health and wellness. For those with pre-existing medical conditions, claiming all the nutrients each human requires is dangerous.

Beyond these health and wellness concerns, among those apathetic toward food, Soylent may find a market as a niche product. Those who only see meals in terms of their utility and functionality, who want to optimize their daily routine, allowing more time for them to do what they love,

perhaps being more productive, may gravitate toward Soylent.

For most of us, however, food is more than utility and functionality. It represents socialization, if not celebration, with family and friends. It is tied to culture and tradition. By sharing a meal we create and maintain relationships. Some obtain their identity through the food they consume. As one journalist concluded, "And like sex, food is fraught with emotional, psychological, social, cultural, gender and religious associations."²²

The bottom line: Soylent likely will not lead to the end food, whether traditional or substitutional. The product represents a convenient, healthy, relatively affordable alternative. We may see it used in combination with traditional food or animal product substitutes. For this middle way, users can drink it when they want to; they can eat food when they desire both sustenance and pleasure.

9. Conclusion

The seven for-profit companies profiled in this book are leading the reinvention of food and condiments. Their scientists, entrepreneurs and funders want to spark a revolution that will remake our relationship with our planet and animals. Taking advantage of new technologies and changing tastes, they want to develop food products that will compete against the cheap, but unhealthy, snack, junk, and fast foods, linked to obesity, diabetes, and malnutrition, found all around us.

These firms want us to rethink how we get salt, mayonnaise, animal products, such as cheese, eggs, and meat, and even our food. This reassessment will occur in light of animal welfare ethical quandaries, human health risks, resource scarcities, and environmental concerns.

A blend of approaches to food may evolve, with Rosa Labs' Soylent remaining a niche product. We may see plant-based protein, in the form of cheese, eggs, meat, alongside sustainably-raised chickens and cows and less meat-intensive diets. A healthy attitude to food rests on balancing different objectives, not allowing claims of one group, whether animal ethicists or environmental activists,

to deny the claims of others. Thus, it currently seems unlikely that in coming decades vegetable-generated beef will constitute the only meat many young people will have ever tasted.

In a world of live and let-live, picking corporate winners and also-rans represents a difficult endeavor. If the link between salt and high blood pressure holds, Nu-Tek Food Science may represent one of the firms most likely to succeed.

With respect to the four plant-based firms, Lyrical Foods (cheese) and Hampton Creek (eggs) seem poised to take advantage of their technologies, funding, and consumers search for healthier, more sustainable products. Likewise, Beyond Meat will likely successfully meet the growing demand for healthier, more sustainable chicken strips and beef burgers.

The disruptive efforts of Impossible Foods and possibly Modern Meadow will force some of us to reassess how we get animal protein, particularly beef. In fulfilling the growing demand for healthier, more sustainable beef, these producers of artificial meat, along with Beyond Meat, whether plant-based or cultured, face the

“yuck” factor. It’s a nice idea, but not for me.

Theoretically, it would be simpler and cheaper just to stop eating meat (or meat-like products) and become a vegetarian or a vegan, living on vegetables, fruits, nuts, and grains. However, this is not likely for most of us.

Most humans like meat and want to continue eating it. We have a strong tendency to enjoy meat. We crave meat and have evolved to eat it. Thus, it is unlikely whether beef from plants or lab-grown will become a mass substitute to going vegan or vegetarian.

With future technological advancements with respect to synthetic fat, blood vessels, and other vascular structures that give beef its mouthfeel and taste, it seems likely that companies, especially Impossible Foods, will be able to engineer plant-based products that are identical with beef in almost every way. Some day, it will come raw and be sold in the butcher aisle. It will be free of contaminants and include added ingredients, such as Omega-3, not naturally found in beef. Although removing the need for animals to die in production process, it is unclear whether carnivores will be irked by products, such as artificial beef, pretending to be “real” meat. In short,

Impossible Foods, and even Beyond Meat, face a marketing challenge in wooing beef lovers.

Some, especially vegans and vegetarians, among others, deeply distrust processed foods. Although traditional foods, such as cheese, yogurt, and beer, are engineered, the beef offered by Impossible Foods, Beyond Meat, and especially by Modern Meadow, with its in vitro meat regarded somehow as "unnatural," fly in the face of current food trends favoring whole, fresh, local, unprocessed foods, mostly plants and vegetables. By preparing a meal consisting of "real" food, more proactive wellness consumers are trying to eat what nature gives them, avoiding processed foods, at least to some degree. The movement to eating more organic foods and fewer animal products typically shuns processed foods. Although fresh, organic produce is expensive for consumers, it is low-tech. These protein substitutes, especially meat, constitute processed foods. Beef and possibly chicken may be viewed, at least by some, as another artificial product offered by the broken, commercial food industry. Those wary of processed foods may be suspicious of all the ingredients,

even if all natural, animal-free, and without costs to the environment and human health.

If beef substitutes become cost effective and thus commercially viable, it is uncertain whether Beyond Meat and Impossible Foods will reach the scale and market values of Internet firms. To gain greater acceptance, as noted, these companies will likely switch from frozen to raw meat. However, food represents a difficult nut to crack if it is perishable. Thus, it is harder to create scalable, high margin, perishable food businesses.

However, even if a small percentage of U.S. customers switch from real chicken or beef to plant-based meat, the market would be huge. Validating venture capitalists' funding, these substitute products would then represent a transformative, disruptive technology. As traditional food companies lose market share to upstarts, Unilever's withdrawn lawsuit against Hampton Creek's Just Mayo likely represents the opening salvo in the coming struggle for profits.

As consumers, scientists, entrepreneurs, and funders face the problem of the impact of foods on human health and the environment, from a policy perspective, regulators most

strive to keep pace with emerging trends and developments. The U.S. Food and Drug Administration must review its regulations, beginning with the definition of mayonnaise, in light of plant-based animal products. The federal regulators must also assess their future response to the commercialization of cultured meat. Apart from regulation, technical and cost factors weigh against Modern Meadow's successful development of beef, but not leather. Beyond any specific product, such as lab-grown meat, the federal regulatory process must evolve to deal with how people are starting to eat, now and in the future.

Today, the federal food regulatory process represents a complex web. Fifteen federal regulatory agencies have a role in making certain that the food Americans eat is safe. Proposing the creation of a new federal unit, the Food Safety Administration to be housed in the U.S. Department of Health and Human Services (HHS), in 2015 the Obama administration sought to untangle the current bureaucratic and fragmented web that has defied streamlining for decades.¹ According to the Government Accountability Office, the current system is "high-risk" because of "inconsistent oversight, ineffective coordination, and

inefficient use of resources.''² Furthermore, as a result of foodborne illnesses, each year some 48 million Americans get sick, 128,000 are hospitalized with food-related illnesses, and 4,000 die from food-related diseases.³

For proponents of consolidation, a single food entity, whether housed in the HHS or a stand-alone agency,⁴ would ensure that one regulatory body is accountable for the entire spectrum of food safety issues, including applied research, prevention, inspection, labeling, enforcement, and outbreak response. The single entity would thus improve governmental efficiency. However, entrenched bureaucracies are difficult to meld. The Department of Agriculture and the Food and Drug Administration, the two key food safety agencies, have different mandates, operate different types of inspection programs, and require different levels of education and training for inspectors. Also it is uncertain whether a single agency would unnecessarily compromise food safety efforts by lowering the standards for meat and poultry inspection.

I want to conclude on an optimistic, but speculative, note. The future is wide open. Beyond chickens and cows, the for-profit companies profiled in this book and other

emerging startups can go beyond imitating known animal products, including cheese, eggs, and meat. They may create entirely novel food products, raising opportunities for scientists, entrepreneurs, and funders, but new regulatory challenges.
